Forests

Forest is the house to many living organisms.

Forests help in maintaining the water cycle on earth. Plants absorb water from the soil through their roots.

Forests help in maintaining the temperature and oxygen level of the atmosphere.

Forests being a huge reserve of plants and trees, they play a significant role in balancing oxygen level in the atmosphere.

Forests help in preventing global warming. The increased amount of carbon dioxide (greenhouse gas) in the atmosphere results in the greenhouse effect and thus causes global warming.

Forests prevent soil erosion. Trees present in the forests hold the soil particles strongly with the roots and prevent them from erosion.

Deforestation

Forest depletion and land degradation have inevitable associations with extensive loss of habitat and biodiversity
